January 13, 2020

## **Elevated Influenza Activity: Influenza B/Victoria and A(H1N1)pdm09 Viruses are the Predominant Viruses**

### **Summary**

Influenza activity remains high in the United States. Ongoing elevated activity is due to influenza B/Victoria viruses, increasing circulation of influenza A(H1N1)pdm09 viruses, and low levels of influenza B/Yamagata and influenza A(H3N2) viruses. The Centers for Disease Control and Prevention (CDC) influenza forecasts suggest that national influenza activity will remain elevated for several more weeks. Because influenza activity is elevated and both influenza A and B virus infections can cause severe disease and death, this health alert serves as a reminder that early treatment with antiviral medications improves outcomes in patients with influenza. Early treatment with antiviral medications is recommended for hospitalized patients and high-risk outpatients, including children younger than two years. Clinicians should continue efforts to vaccinate patients for as long as influenza viruses are circulating, and promptly start antiviral treatment of severely ill and high-risk patients with suspected influenza without waiting for laboratory confirmation.

As of January 13, 2020, Delaware county has 11 influenza-associated hospitalizations for the 2019-2020 influenza season. Ages range from 9 to 92 years of age with an average age of 59 years median age of 69 years. 63.6% of cases are male. 54.5% of cases had Type A influenza. 50% of cases were unvaccinated (n=10).

### **Background**

In the United States, influenza activity remains elevated and widespread, and the season is likely to last several more weeks (see CDC FluView report for details: <https://www.cdc.gov/flu/weekly/index.htm>). Since early this season, influenza B viruses, specifically B/Victoria viruses, have been reported more frequently than other influenza viruses, followed by A(H1N1)pdm09. Different viruses have predominated in different parts of the country and among different age groups. Influenza B viruses can cause severe illness in people of all ages, including children. In past seasons, the percentage of influenza B viruses detected in children who died with influenza has generally been higher than the percentage of B viruses detected in the general pediatric population, and pediatric mortality from influenza B-associated hospitalizations has been reported to be higher than with influenza A-associated hospitalizations.<sup>4</sup> So far this season, influenza B virus infections account for about half of hospitalizations reported through CDC's laboratory-confirmed influenza hospitalization surveillance network and the majority of reported influenza-associated pediatric deaths (<https://www.cdc.gov/flu/weekly/index.htm>). Influenza A(H1N1)pdm09 viruses are increasing and becoming predominant in some regions. These viruses can also cause severe illness, particularly in adults not originally exposed to currently circulating A(H1N1)pdm09 viruses.<sup>5</sup> Influenza A(H1N1)pdm09 viruses currently comprise the majority of the other half of hospitalizations reported through CDC's laboratory-confirmed influenza hospitalization surveillance network.

### **Recommendations**

Influenza vaccination and prompt antiviral treatment of high-risk outpatients and hospitalized patients with suspected influenza.

### **All People Six Months and Older Who Have Not Yet Received an Influenza Vaccine this Season Should Be Vaccinated Against Influenza**

All available vaccine formulations this season contain A(H3N2), A(H1N1)pdm09, and B/Victoria virus strains.<sup>21</sup> The 2019-2020 U.S. quadrivalent influenza vaccines contain these and an additional influenza B/Yamagata virus. CDC does not recommend one influenza vaccine formulation over another.

## All Hospitalized, Severely Ill, and High-Risk Patients with Suspected or Confirmed Influenza, Regardless of Influenza Vaccination Status, Should Be Treated with Antivirals As Soon As Possible After Onset of Illness

Antiviral treatment is recommended as early as possible for any patient with suspected or confirmed influenza who—

- 1) Is hospitalized.
- 2) Has severe, complicated, or progressive illness. This may include outpatients with severe or prolonged progressive symptoms or patients who develop complications such as pneumonia but who are not hospitalized.
- 3) Is at high risk for influenza complications but not hospitalized. This includes—
  - Children younger than two years. Although children younger than five years are considered at higher risk for complications from influenza, the highest risk is for those younger than two years.
  - Adults 65 years and older.
  - People with chronic pulmonary (including asthma), cardiovascular (except hypertension alone), renal, hepatic, hematological (including sickle cell disease), and metabolic (including diabetes mellitus) disorders.
  - People with neurologic and neurodevelopment conditions, including disorders of the brain, spinal cord, peripheral nerve, and muscle, such as cerebral palsy, seizure disorder, stroke, intellectual disability, moderate to severe developmental delay, muscular dystrophy, or spinal cord injury.
  - People with immunosuppression, including that caused by medications or by HIV infection.
  - Women who are pregnant or postpartum (within two weeks after delivery).
  - People younger than 19 years who are receiving long-term aspirin therapy.
  - American Indians and Alaska Natives.
  - People with extreme obesity (i.e., body mass index is equal to or greater than 40).
  - Residents of nursing homes and other chronic care facilities.

Antiviral treatment has shown clinical and public health benefit in reducing illness and lessening severe outcomes of influenza based on evidence from randomized controlled trials, meta-analyses of randomized controlled trials, and observational studies during past influenza seasons and during the 2009 H1N1 pandemic. Influenza antiviral medications are most effective in treating influenza and reducing complications when treatment is started early (within 48 hours of illness onset). Some studies suggest clinical benefit among hospitalized patients and young children with febrile illness even when treatment was started three to five days after illness onset.

### Antiviral Treatment in Non-High-Risk Patients with Uncomplicated Influenza

Antiviral treatment can benefit other individuals with influenza. While current guidance focuses on antiviral treatment of those with severe illness or at high risk of complications, antiviral treatment may be prescribed for any previously healthy (non-high risk) outpatient with suspected or confirmed influenza who presents within two days after illness onset. Multiple randomized controlled clinical trials (RCTs) and meta-analyses of RCTs have demonstrated efficacy of early initiation of treatment (started within 48 hours of illness onset) with neuraminidase inhibitors in reducing duration of fever and illness symptoms by about a day compared with placebo in otherwise healthy children and adults with uncomplicated influenza. Clinical judgment—considering the patient's disease severity and progression, age, likelihood of influenza, and time since onset of symptoms is important when making antiviral treatment decisions for outpatients who are not at increased risk for influenza complications.

### **Choice of Antiviral Medication**

Four influenza antiviral medications approved by the U.S. Food and Drug Administration (FDA) are recommended for use in the United States during the 2019-2020 influenza season.

Three drugs are chemically related antiviral medications known as neuraminidase inhibitors: oral oseltamivir phosphate (available as a generic version or under the trade name Tamiflu®), inhaled zanamivir (trade name Relenza®), and intravenous peramivir (trade name Rapivab®). These medications block the viral neuraminidase enzyme and have activity against both influenza A and B viruses.

The fourth drug is oral **baloxavir marboxil** (trade name Xofluza®), which is active against both influenza A and B viruses but has a different mechanism of action. Baloxavir is a cap-dependent endonuclease inhibitor that interferes

with viral RNA transcription and blocks virus replication. In October 2019, FDA approved an indication for baloxavir treatment of acute uncomplicated influenza within two days of illness onset in people 12 years and older at high risk of developing influenza-related complications, based upon the findings of a clinical trial.<sup>22</sup> In the clinical trial of early initiation of antiviral treatment for uncomplicated influenza in high-risk adolescents and adults, baloxavir was superior to placebo and had similar overall efficacy to oseltamivir in the time to alleviation of symptoms. There are no available data for baloxavir treatment of influenza in pregnant women, immunocompromised people, those with severe disease, or hospitalized patients.

Recommended ages for treatment and prevention with antiviral medications are summarized in the table below. Dosing and more detailed treatment considerations can be found in the Influenza Antiviral Medications: Summary for Clinicians (<https://www.cdc.gov/flu/professionals/antivirals/summary-clinicians.htm>).

Antiviral	Route	Treatment	Chemoprophylaxis	Most Common Adverse Events
Oseltamivir	Oral and Enteric	Any Age	≥ 3 months	Nausea, vomiting, headache*
Zanamivir	Inhaled	≥7 years	≥ 5 years	Bronchospasm
Peramivir	Intravenous	≥2 years	N/A	Diarrhea
Baloxavir	Oral	≥12 years	N/A	None more common than placebo

\*Nausea and vomiting are generally transient and can be mitigated if oseltamivir is taken with food

For outpatients with acute uncomplicated influenza, oral oseltamivir, inhaled zanamivir, intravenous peramivir, or oral baloxavir may be used for treatment.

The recommended treatment course for uncomplicated influenza is—

- One dose twice daily of oral oseltamivir for five days, or
- One dose twice daily of inhaled zanamivir for five days, or
- One dose of intravenous peramivir, or
- One dose of oral baloxavir.

Oral or enterically-administered oseltamivir is the only recommended antiviral medication for treating hospitalized patients with suspected or confirmed influenza and patients with severe or complicated illness with suspected or confirmed influenza (e.g., pneumonia, exacerbation of underlying chronic medical condition) who are not hospitalized. Please see the Influenza Antiviral Medications: Summary for Clinicians (<https://www.cdc.gov/flu/professionals/antivirals/summary-clinicians.htm>) for considerations regarding dosing and duration of antiviral treatment for patients with severe or complicated influenza. There are insufficient data for use of inhaled zanamivir, intravenous peramivir, and oral baloxavir in patients with severe influenza disease.

Oral oseltamivir is preferred for treatment of pregnant women. Oseltamivir has been shown to be safe for treating pregnant women, and pregnant women are recommended to receive the same antiviral dosing as non-pregnant people. Baloxavir is not recommended for treating women or breastfeeding mothers, as there are no available efficacy or safety data.

#### **Timing of Treatment and Implications for Patient Evaluation, Treatment, and Testing**

Clinical benefit is greatest when antiviral treatment is administered as close to illness onset as possible. Therefore, antiviral treatment should be started as soon as possible and should not wait for laboratory confirmation of

influenza. Ideally, treatment should be initiated within 48 hours of onset of symptoms. However, antiviral treatment initiated later than 48 hours after illness onset can still be beneficial for some patients.

A history of current season influenza vaccination does not exclude a diagnosis of influenza in an ill child or adult. High-risk patients should be advised to call their healthcare provider promptly if they have symptoms of influenza.

Specimens from all hospitalized patients with suspected influenza should be tested with molecular assays with high sensitivity and specificity since influenza testing can help inform clinical management and prompt implementation of infection prevention and control measures for influenza. Molecular assays (including reverse transcription polymerase chain reaction [RT-PCR]) should be used for influenza testing of hospitalized patients. Treatment should be empiric and should start as soon as possible. Treatment should not wait for laboratory confirmation.

## Figure: Guide for considering influenza testing when influenza viruses are circulating in the community (regardless of influenza vaccination history)<sup>1</sup>

### Reporting

Influenza-associated hospitalizations are a class B reportable disease in Ohio, meaning cases are required to be reported by the next business day. Outbreaks of influenza are class C reportable in Ohio, meaning outbreaks should be reported by the next business day. Please report all cases to the Delaware General Health District (DGHD) by calling (740) 203-2039 or fax reports to our secure fax line- (740) 203- 2044.

### For more information

The Delaware General Health District (DHGD) sends out a monthly flu report via email. To receive these emails, contact the DGHD at 740-203-2039.
